Problem: Data-efficient Imitation Learning for Target Task by Utilizing Prior Robotic Dataset

Algorithm:

- 1. For MDP problem $\mathcal{M}(S, \mathcal{A}, \mathcal{P}, \mathcal{R}, \gamma, \rho_0)$, learn policy π : $\hat{z} = \pi(o_{fS})$ to maximize the discounted sum of rewards $(\mathbb{E}[\sum_{t=0}^{\infty} \gamma^t R(s_t, a_t, s_{t+1})])$ for the task.
- 2. <u>Pretrain and finetune</u> paradigm:
 - a. <u>Predictable</u> Skills Representation Learning from Prior Data

Sequence Sequence O_0 O_t Observation Encoder O_{t+H-1} O_{H-1} (ResNet-18 for image and MLP for low-dim) latent_ Skill Encoder (2-layer LSTM + 2-layer MLP) TD (2-layer Model MLP)

$$egin{aligned} \mathcal{L}_{ ext{TP}}(\omega,\phi) &= \Big(m_{\omega}\Big(\mu(q_{\phi}(z| au_1)),\mu(q_{\phi}(z| au_2))\Big) - t\Big)^2, \ \mathcal{L}_{ ext{Skill}}(\phi,\psi, heta,\omega) &= \mathcal{L}_{ ext{VAE}}(\phi,\psi, heta) + lpha \mathcal{L}_{ ext{TP}}(\omega,\phi) \end{aligned}$$

 $+ \left[\beta \cdot D_{KL}(q_{\phi}(z| au)||p_{ heta}(z|o_0,o_H)) \right]$

Learned VAE prior (2-layer MLP) to encourage <u>sub-trajectories with similar starting and ending observations to have similar latent representations</u>.

Encourage the learned latent space to <u>predict the temporal difference</u> KL divergence: encourage learned skills to be <u>predictable</u>. between two sub-trajectories

Problem: Data-efficient Imitation Learning for Target Task by Utilizing Prior Robotic Dataset **Algorithm:**

- 1. For MDP problem $\mathcal{M}(S, \mathcal{A}, \mathcal{P}, \mathcal{R}, \gamma, \rho_0)$, learn policy π : $\hat{z} = \pi(o_{fs})$ to maximize the discounted sum of rewards $(\mathbb{E}[\sum_{t=0}^{\infty} \gamma^t R(s_t, a_t, s_{t+1})])$ for the task.
- 2. <u>Pretrain and finetune</u> paradigm:
 - b. <u>Retrieval-based</u> Policy Learning using Target Task Data

Retrieval-based data augmentation:

Find top K nearest neighbors from \mathcal{D}_{prior} as augmented data for policy learning and skills representation learning model fine-tuning

end while

Increase the scope of supervision for policy training.

```
While not done do Sample (o_{fs},z) \sim \mathcal{D}_{target} // target dataset sub-traj encoding and frame stack Sample (o'_{fs},z') \sim \mathcal{D}_{ret} // retrieval dataset sub-traj encoding and frame stack \hat{z} \leftarrow \pi(o_{fs}, \mathrm{id} = 0) // predict skill for target dataset sub-traj \hat{z'} \leftarrow \pi(o'_{fs}, \mathrm{id} = 1) // predict skill for retrieval dataset sub-traj // Predict skill for retrieval dataset sub-traj // Compute Policy Loss update \pi on \mathcal{L}_{Policy} via gradient descent fine-tune \mathcal{L}_{Skill} on sub-trajectories sampled from \mathcal{D}_{prior} and \mathcal{D}_{target} // see Algorithm 1
```

Summarization and Personal Thinking

Summarization of innovations:

- 1. Pretrain and finetune paradigm:
 - a. Compared with pretraining policy model on prior task data and then finetuning on target task data, pretraining predictable skills representations as downstream policy model's augmented training data can eliminate harmful effects (harmful effects due to conflicts and divergence between prior and target data when naively training policy on prior and target data).
 - b. Nearest pretrained skills representations can increase the scope of supervision for policy learning, thus lead to better generalization.
- 2. Data-efficient retrieval-based data augmentation:
 - a. Target task data's nearest neighbors from learned skills as data augmentation is dataefficient especially when target data set is small.
 - b. Retrieval-based data augmentation also considers about relevance property and utilizes this property.

Personal thinking of future work:

- 1. Multi task imitation learning and merging two phases into one-stage for better computation efficiency.
- 2. Changing RNN-based encoders and decoders to transformer-based ones for computation efficiency.
- 3. Investigate the effectiveness of this approach with various forms of prior data at different scales (mentioned in paper).
